

Controllers

Prof. Cesar de Prada

Dpt. Systems Engineering and Automatic Control

University of Valladolid, Spain

prada@autom.uva.es

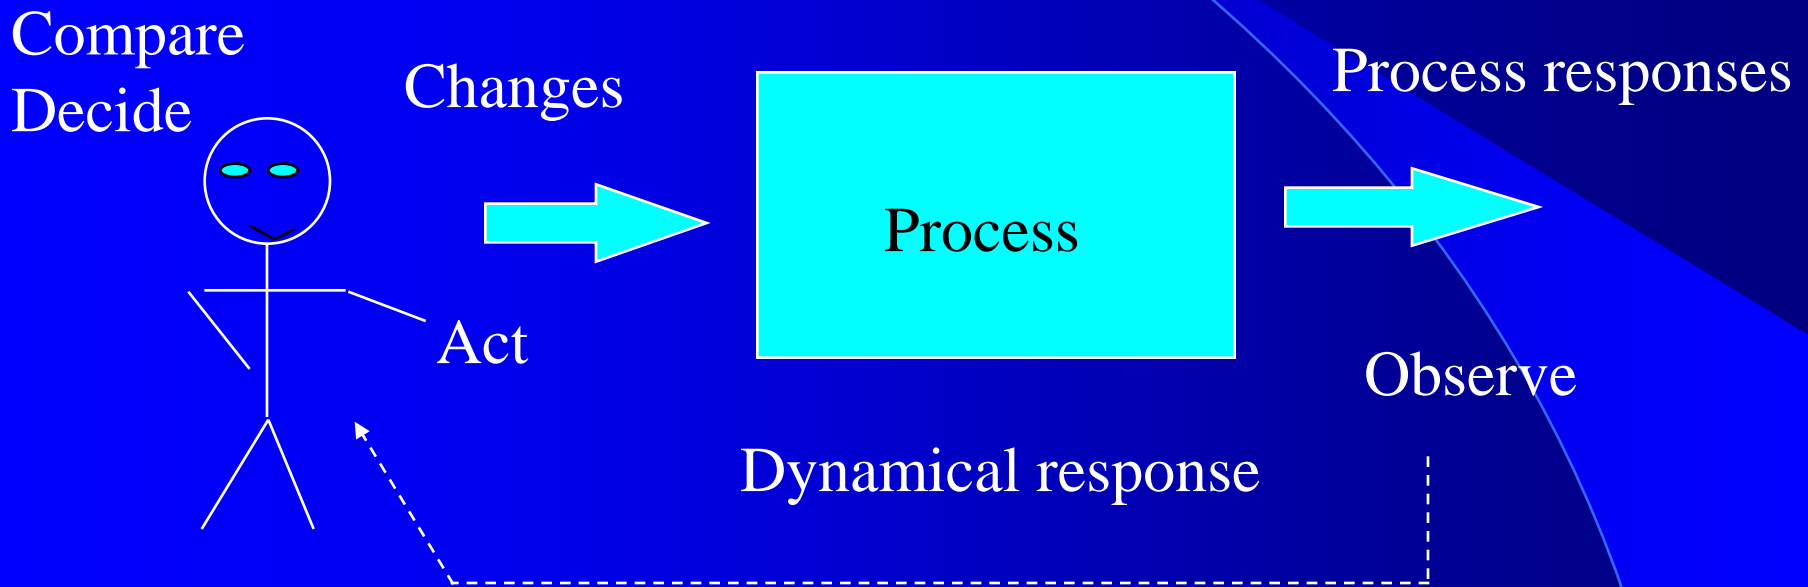

<http://www.isa.cie.uva.es/~prada/>

Manual operation of a process

Observe the level
Compare with desired value
Decide the valve position
Act on the valve

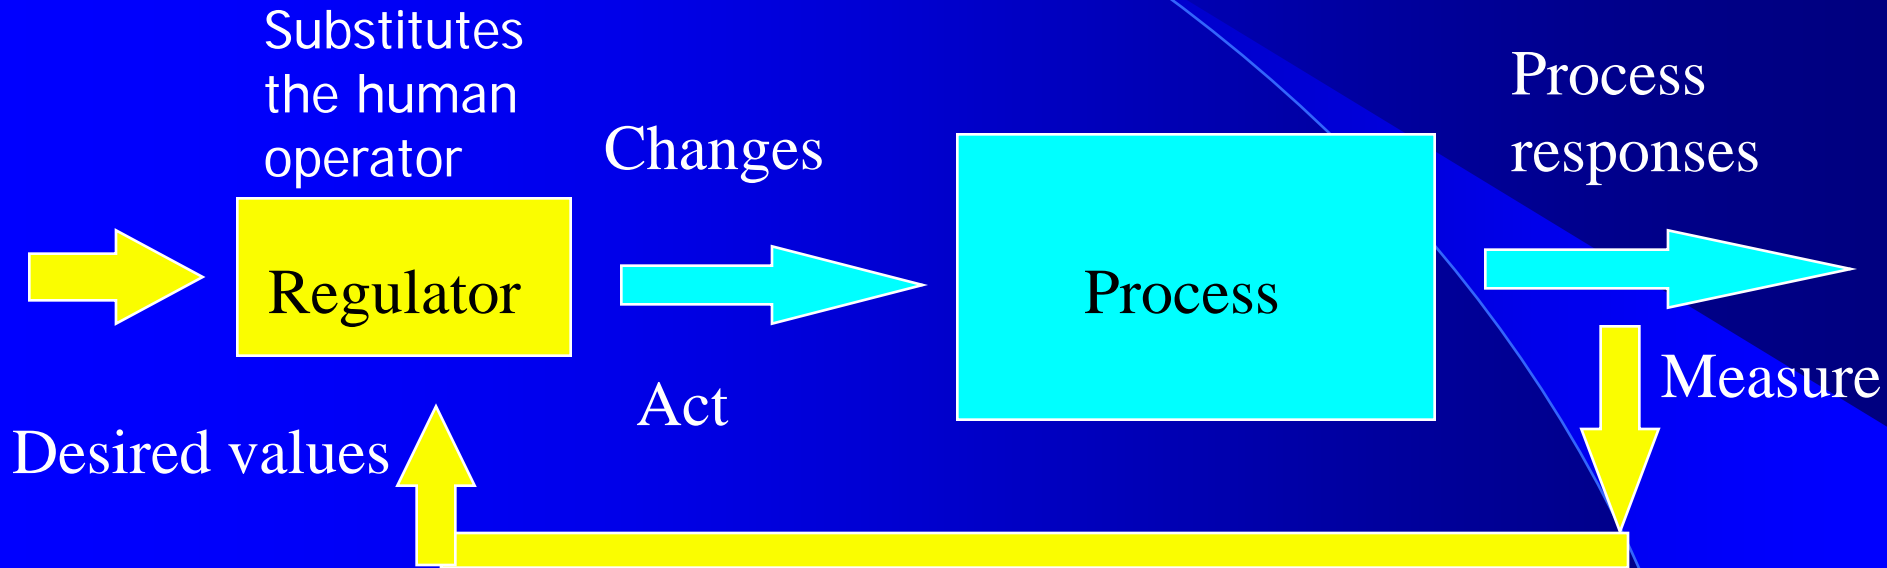

Process operation

Open loop or manual operation

Automatic operation

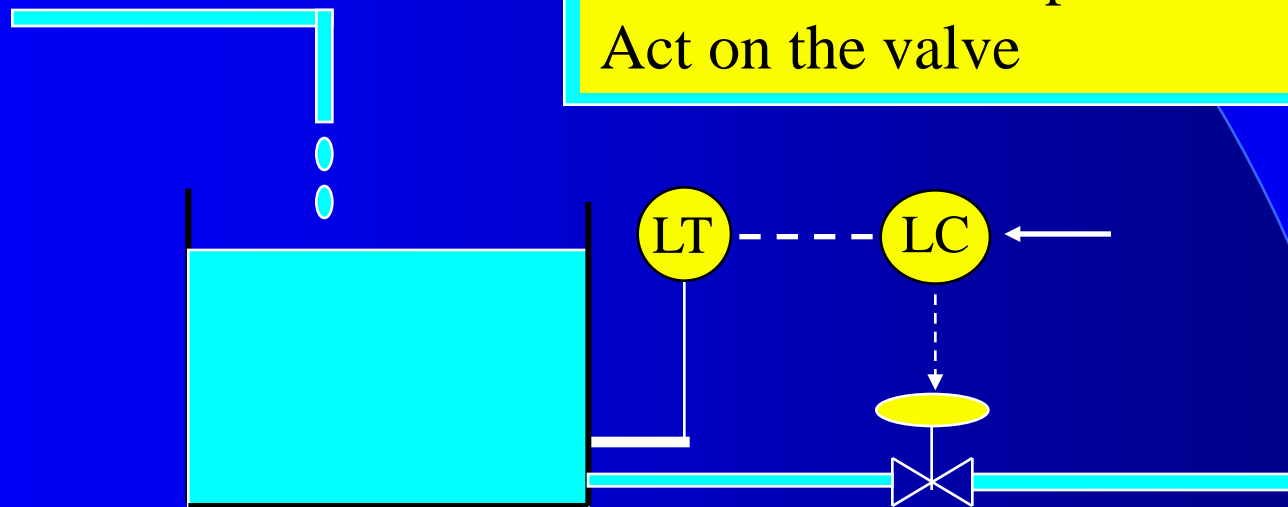

Closed loop or automatic operation

Feedback

Automatic operation

Measure the level
Compare with desired value
Decide the valve position
Act on the valve

Terminology

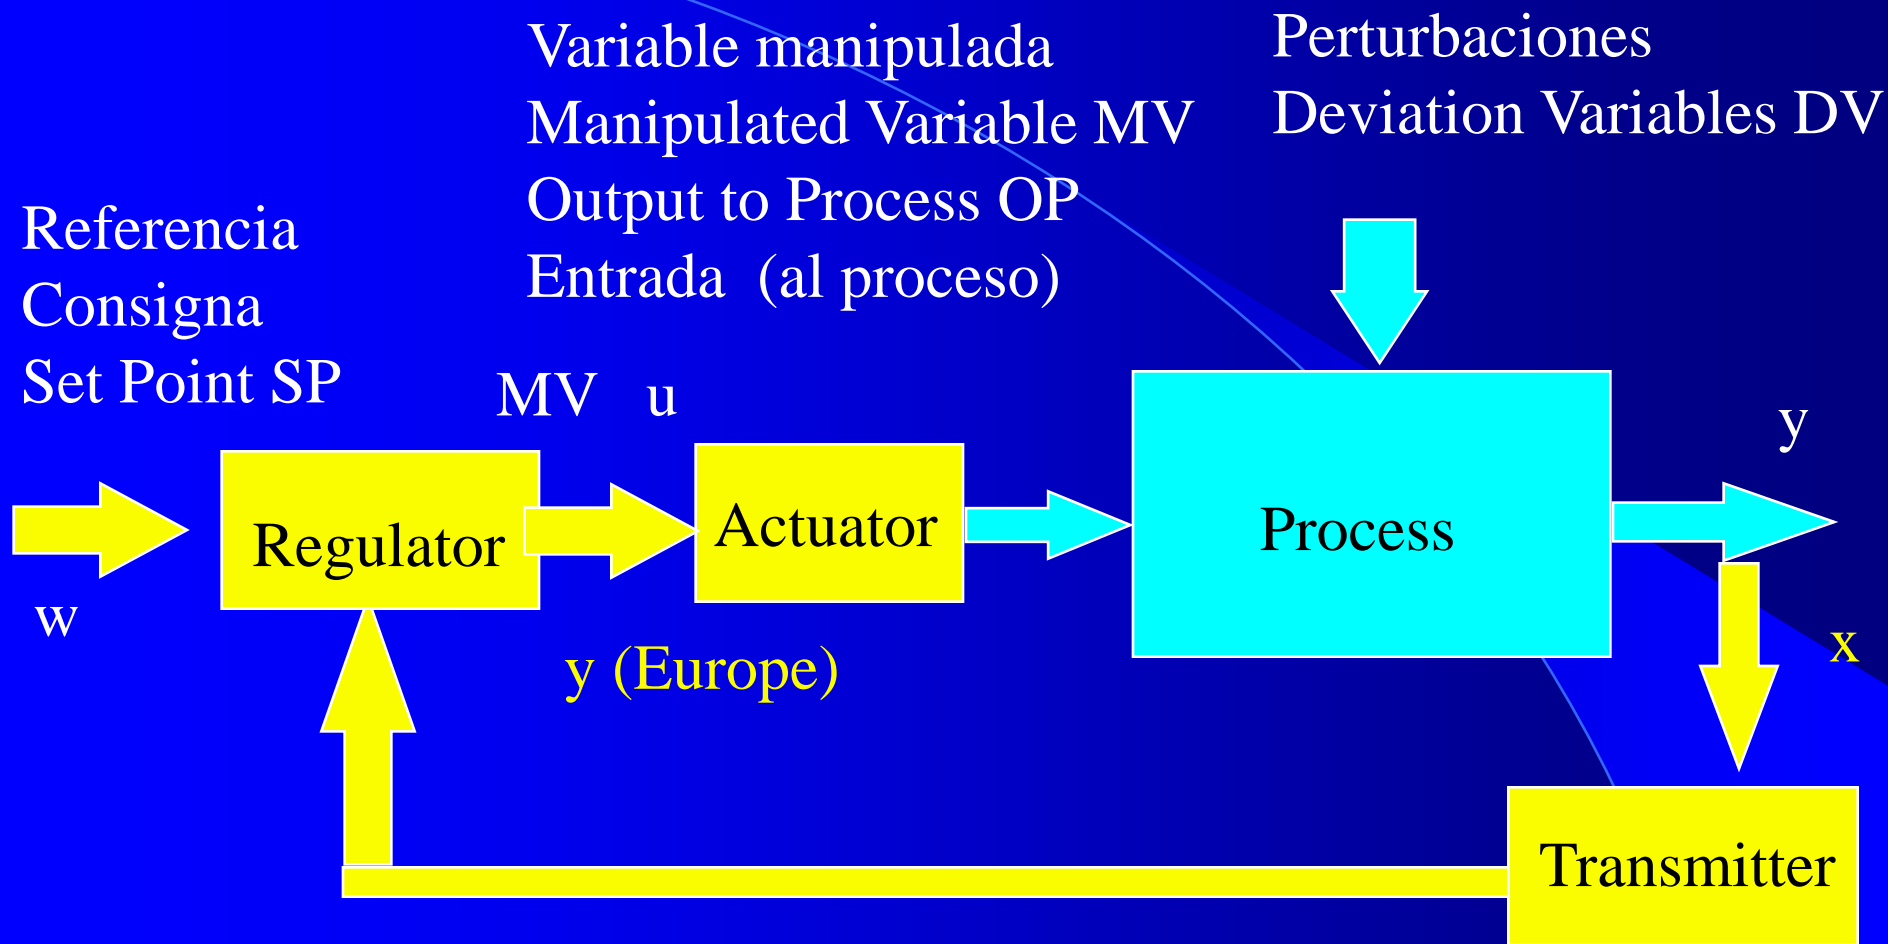

Disturbance

Controlled variable

Set Point

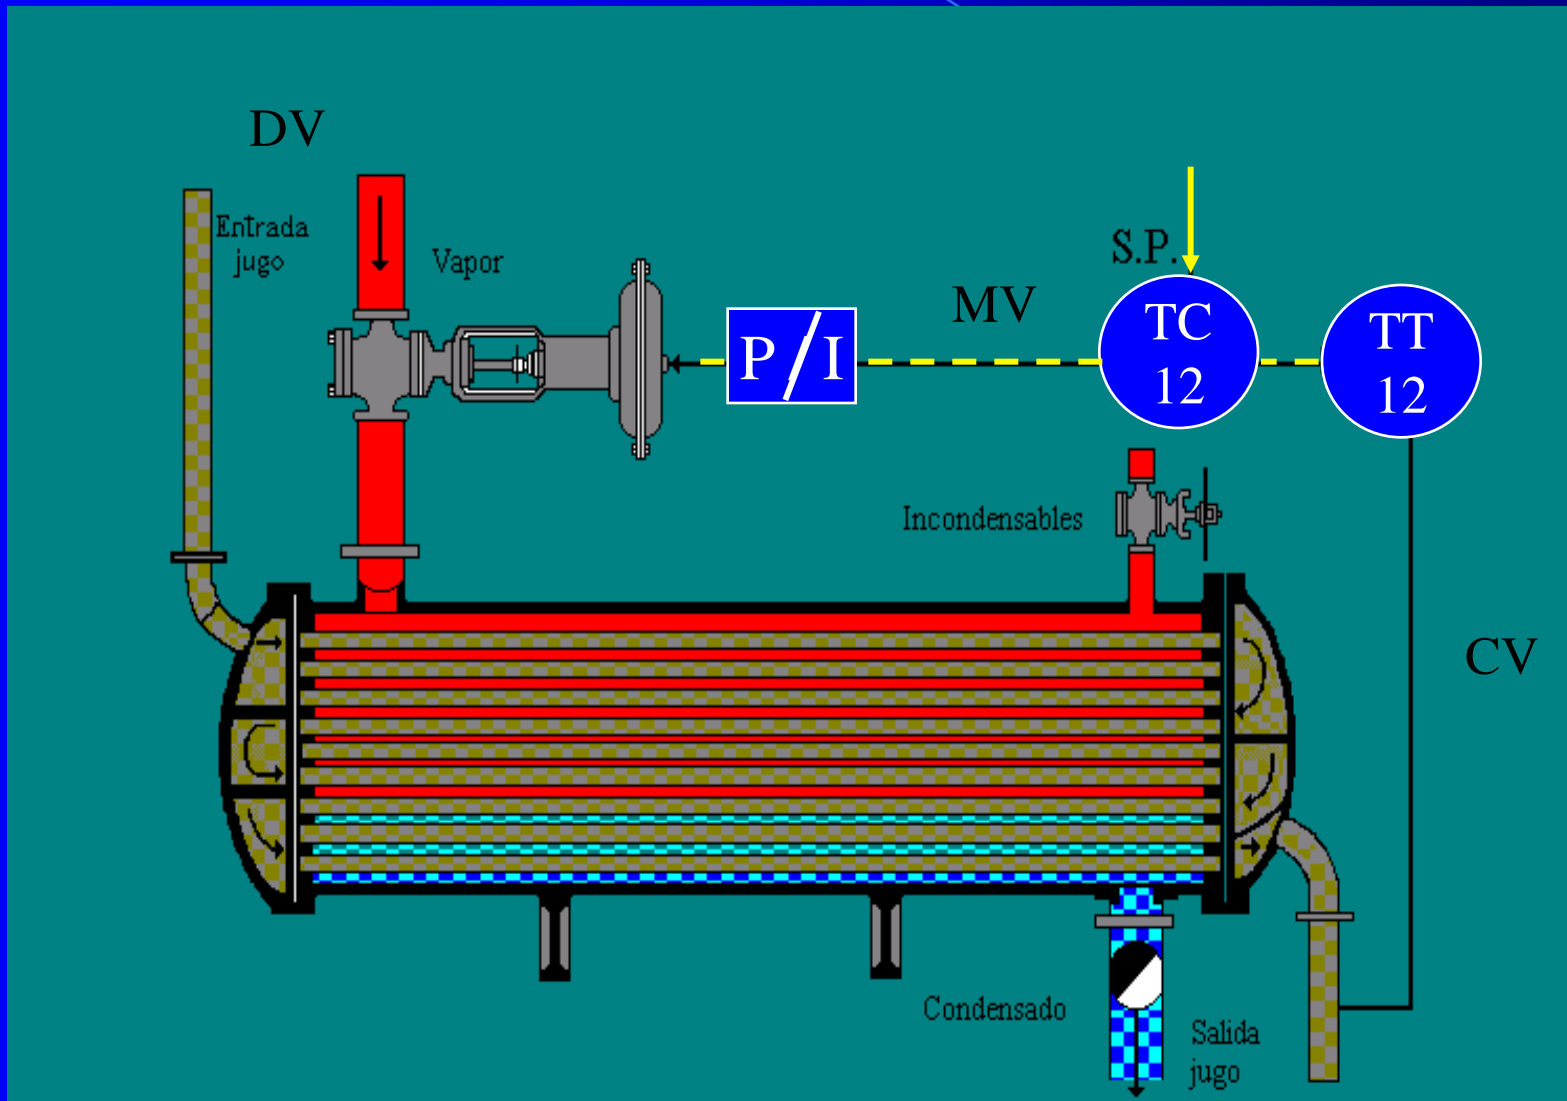

Manipulated
variable

Block Diagram

Variable Controlada
 Controlled Variable CV
 Process Variable PV
 Salida (del proceso)

Heat exchanger

Continuous Control

The controlled variable takes continuous values within a range and the manipulated variable can have any value within a continuous range

On/Off (Logic / Discrete) Control

Variables take a discrete number of values or states and change only at certain time instants

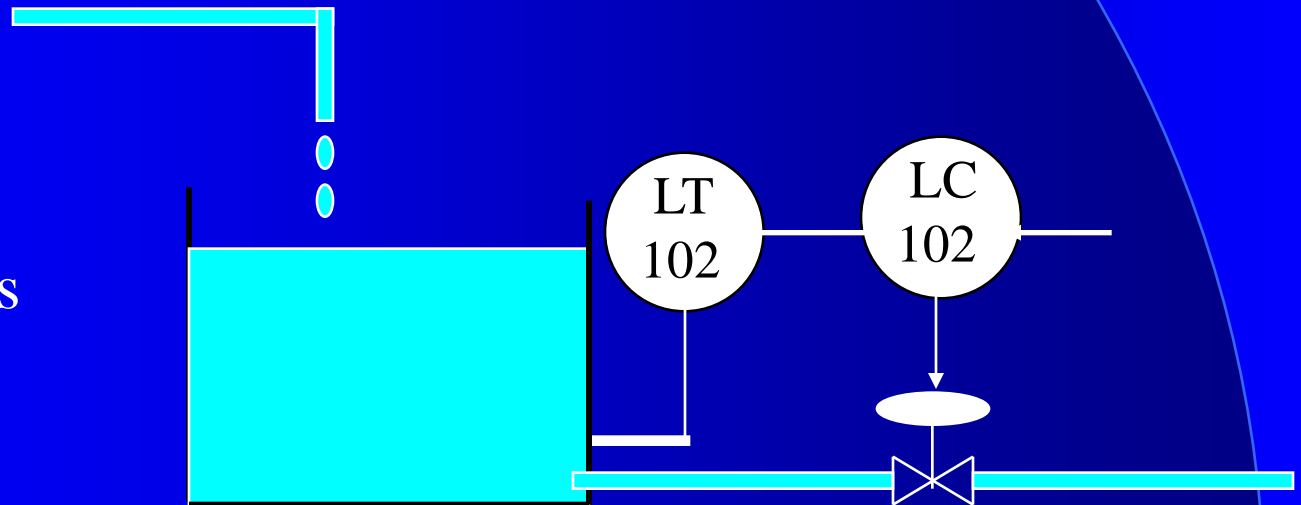

P&I Diagrams

Schematics where process units and instruments are represented using special symbols

Control and measurement instruments are represented by circles with letters and figures

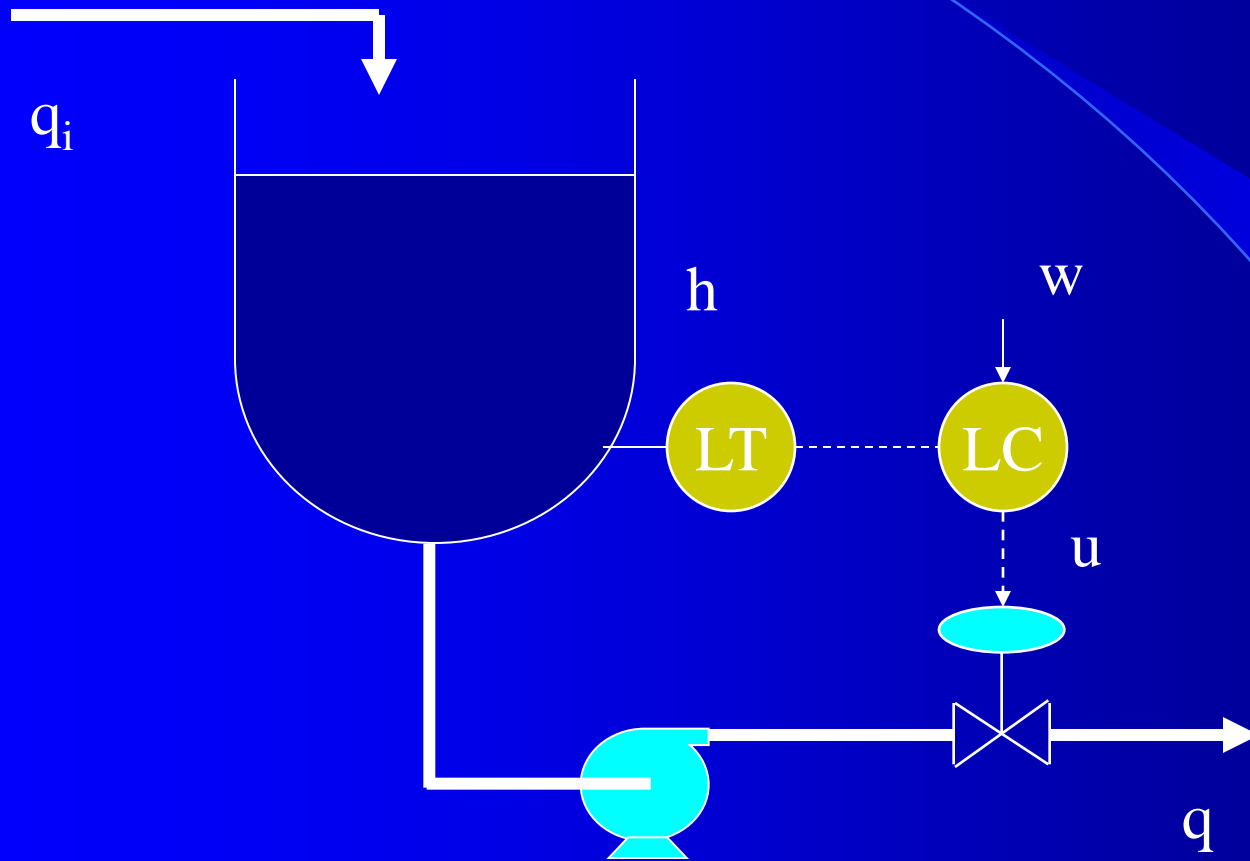

Connection lines

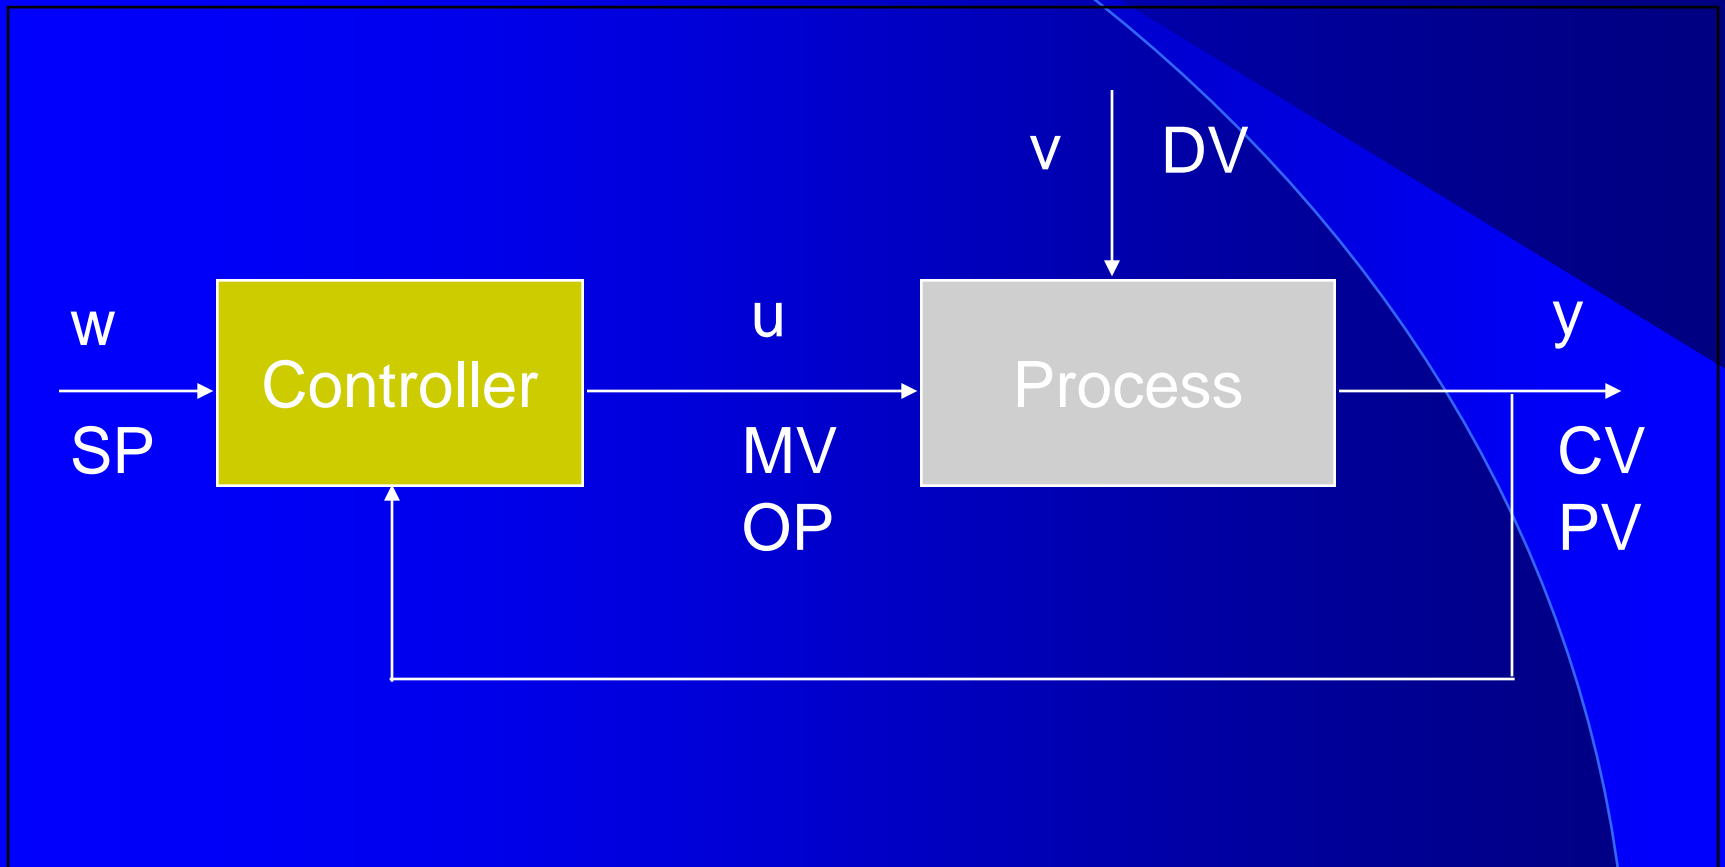

Flow control

Level control

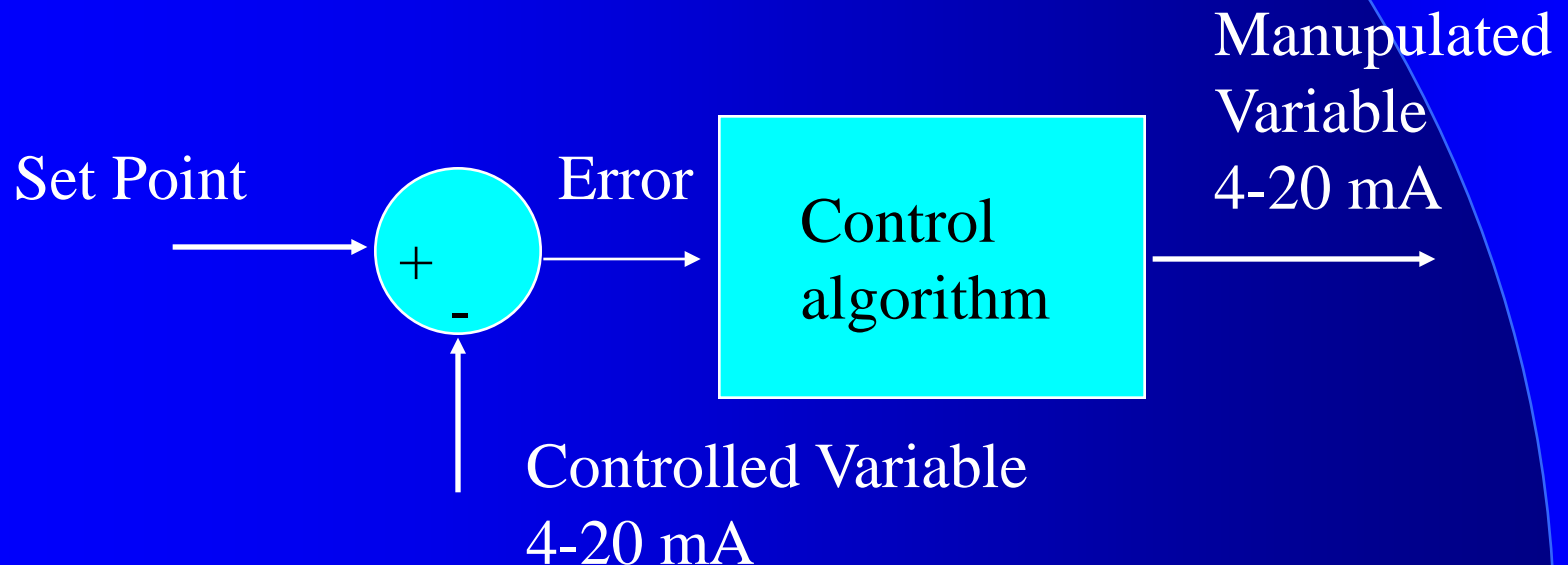

Block Diagram

Controllers

- Generate a normalised signal to the actuator as a function of the values of the controlled variable and its desired value (SP)
- Most used: PID

Proportional controller P

$$u(t) = K_p e(t) + \text{bias}$$

An error of $x\%$ creates an action of $K_p x\%$ on the actuator

bias = manual reset (CV = SP)

Implementation

- Technologies:
 - Pneumatic
 - Electronics
 - Digital
- Loop controllers (PID)
- Within PLC
- Distributed Control Systems (DCS)
- Embedded systems

Normalised signals

Architectures

Diagnosis, configuration

The screenshot displays the DeltaV software interface. On the left, a 3D model of a valve assembly is shown. The main window is titled 'Status - REV8' and contains the following information:

- ValveLink VL2000 Revision B459**
- CTLR1/ID1/C01/P01**
- REV7**
- REV8**
- REVISION7**
- Database**

The 'Current Value' section displays the following data:

Parameter	Current Value
Travel Accumulator	1438628 %
Drive Signal	65.96 %
Cycle Count	163396
Temperature	23.08 C
Input Characteristic	Linear
Output Block Mode	00S
Resource Block Mode	AUTO
Fault State	Clear
Output Block Mode	00S

Three bar charts are shown below the table, representing Temperature (23.08 C), Travel (99.46 %), and Actuator Pressure (16.19 psi). The Temperature chart has a scale from -60 C to 100 C. The Travel chart has a scale from -25 % to 125 %. The Actuator Pressure chart has a scale from 0 psi to 20 psi.

The interface also includes a menu bar (Tag, Diagnostics, Spec Sheet, Tools, Customize ValveLink, Help), a toolbar, and a status bar at the bottom showing 'User: ADMINISTRATOR', '6 object(s)', and 'CAN-CONFIGURE CAN-DOWNLOAD'.

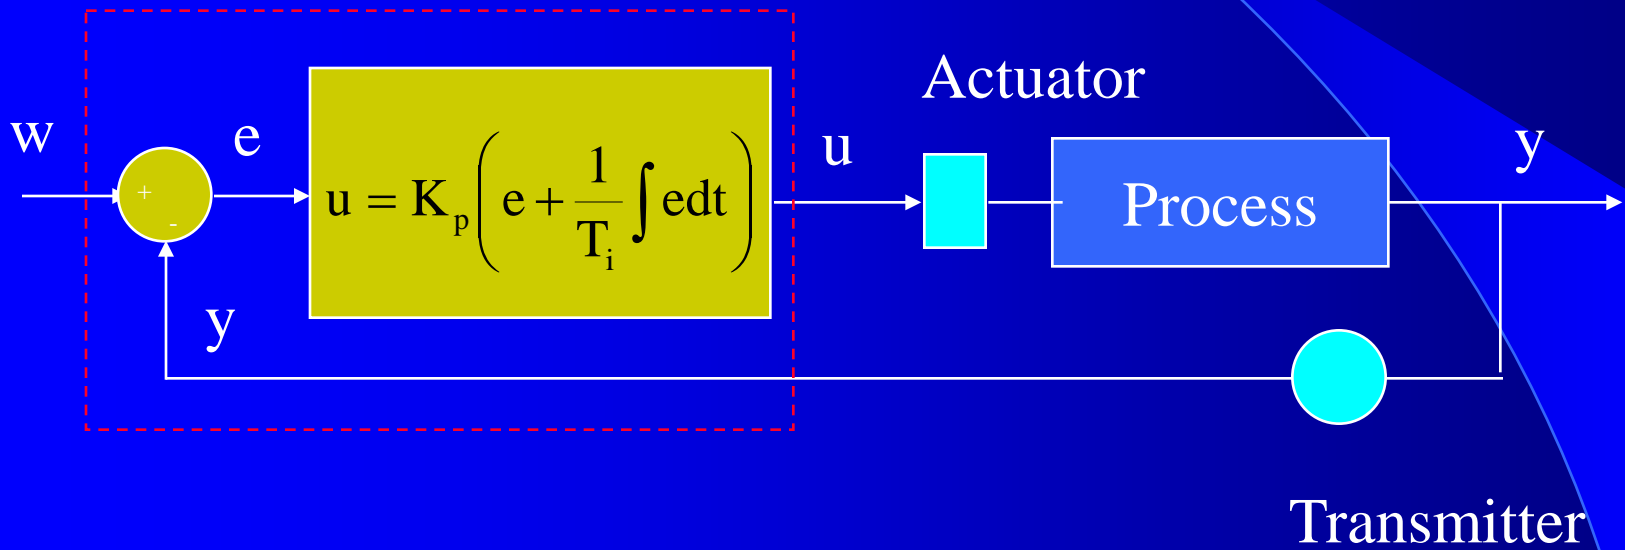

The PID controller

$$e(t) = w(t) - y(t)$$

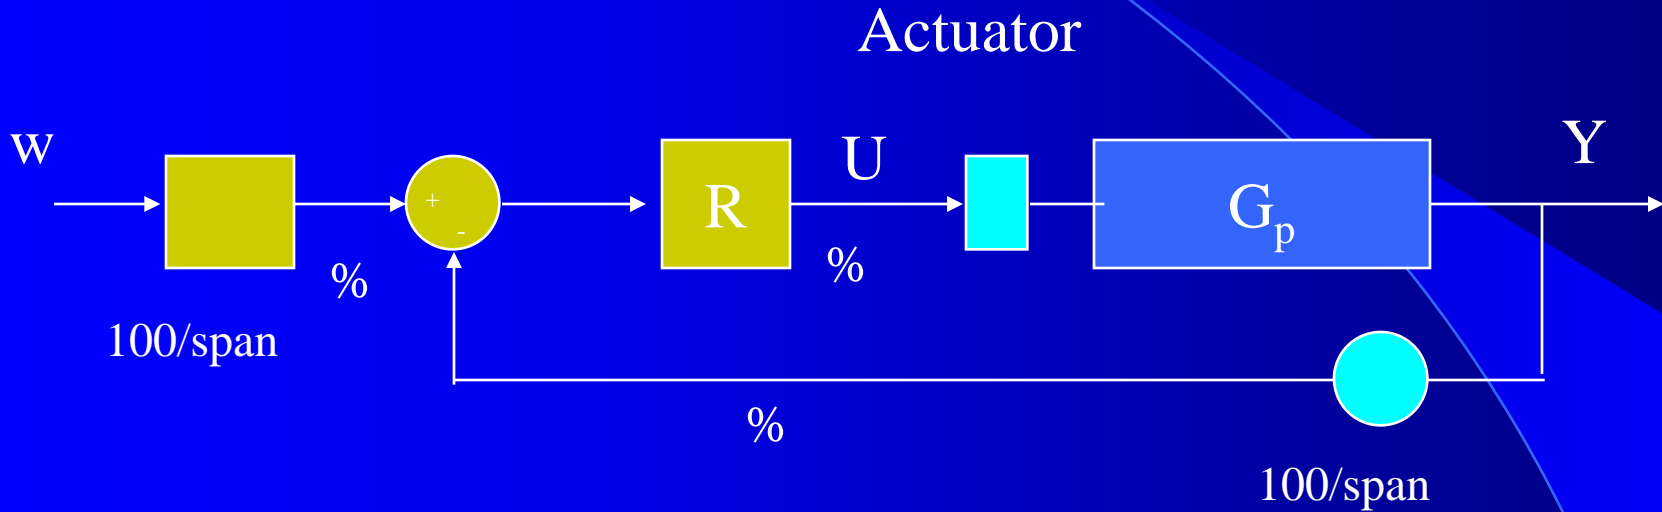

$$u(t) = K_p \left(e(t) + \frac{1}{T_i} \int e(\tau) d\tau + T_d \frac{de}{dt} \right)$$

- **Signal based controller**, no explicit knowledge of the model is used
- 3 main tuning parameters K_p , T_i , T_d
- Several versions

PI

Units

Input and output regulator signals usually are expressed in terms of % of transmitter and actuator respectively

Conversion factors in the controller should correspond to the calibration of the instruments

PID parameters

- K_p gain / Proportional term
 - % span control / % span controlled variable
 - Proportional band $PB=100/ K_p$
- T_i integral time / Integral term
 - minutes o sg. (per repetition) (reset time)
 - repetitions per min = $1/ T_i$
- T_d derivative time / Derivative term
 - minutes o sg.

Proportional controller P

$$u(t) = K_p e(t) + \text{bias}$$

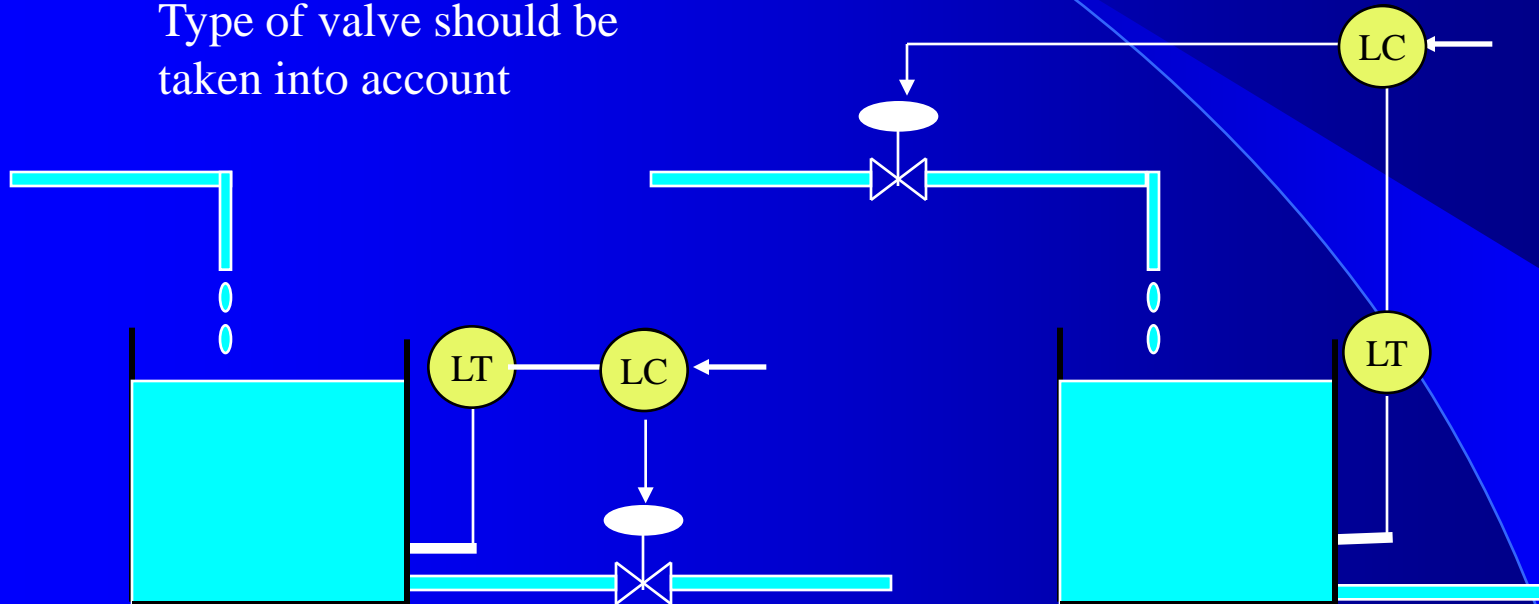

An error of $x\%$ creates an action of $K_p x\%$ on the actuator

bias = manual reset (CV = SP)

Direct / Reverse Acting

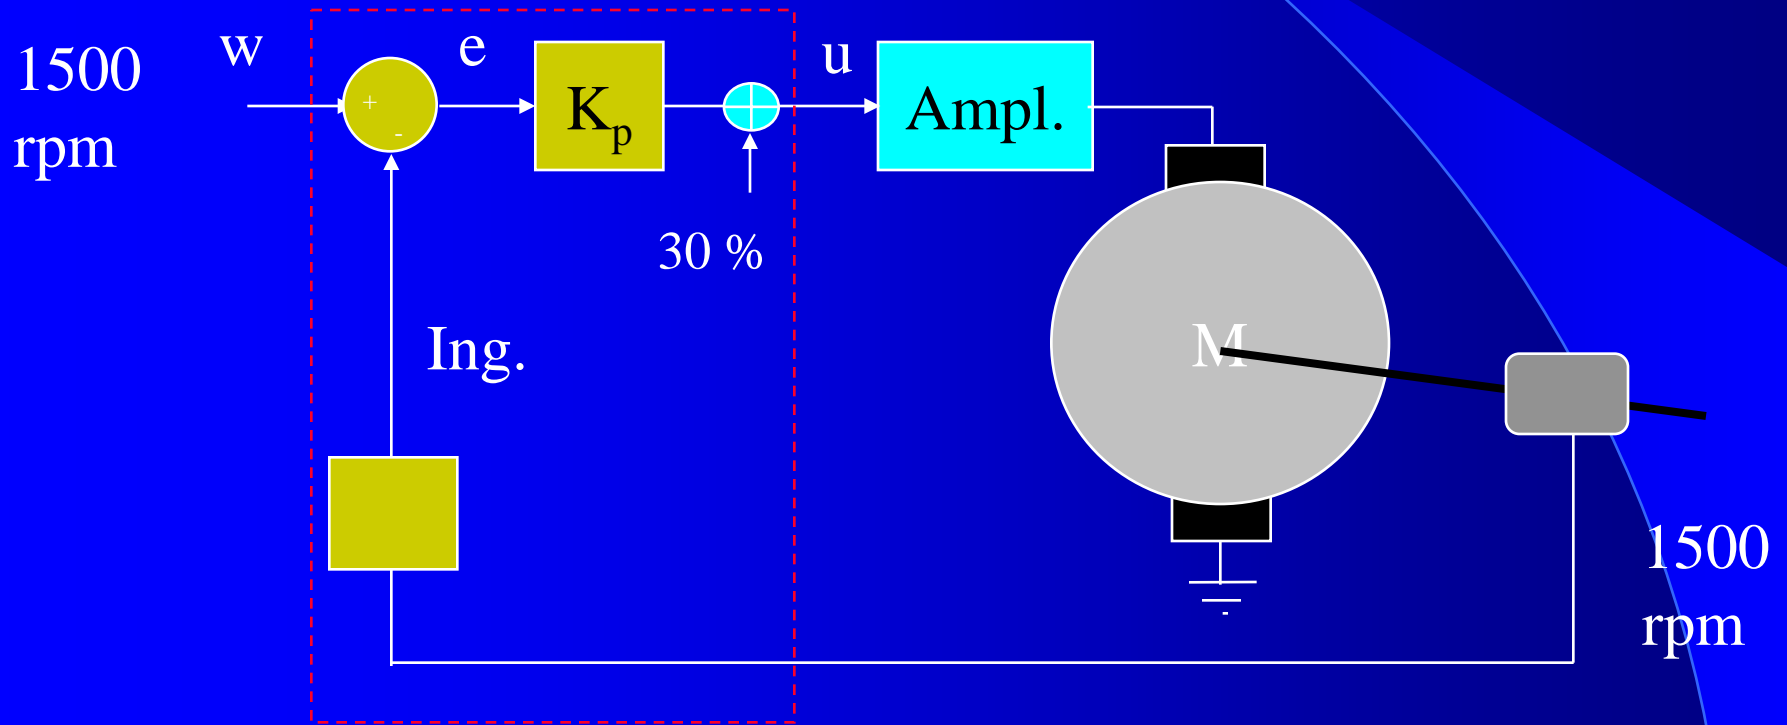

Type of valve should be taken into account

Direct acting controller $K_p < 0$ Reverse acting controller $K_p > 0$

$u(t) = K_p(w - y)$ if y increases, then u decreases if K_p is positive

Proportional action

$$u(t) = K_p e(t) + 30$$

There is only an equilibrium point with zero error

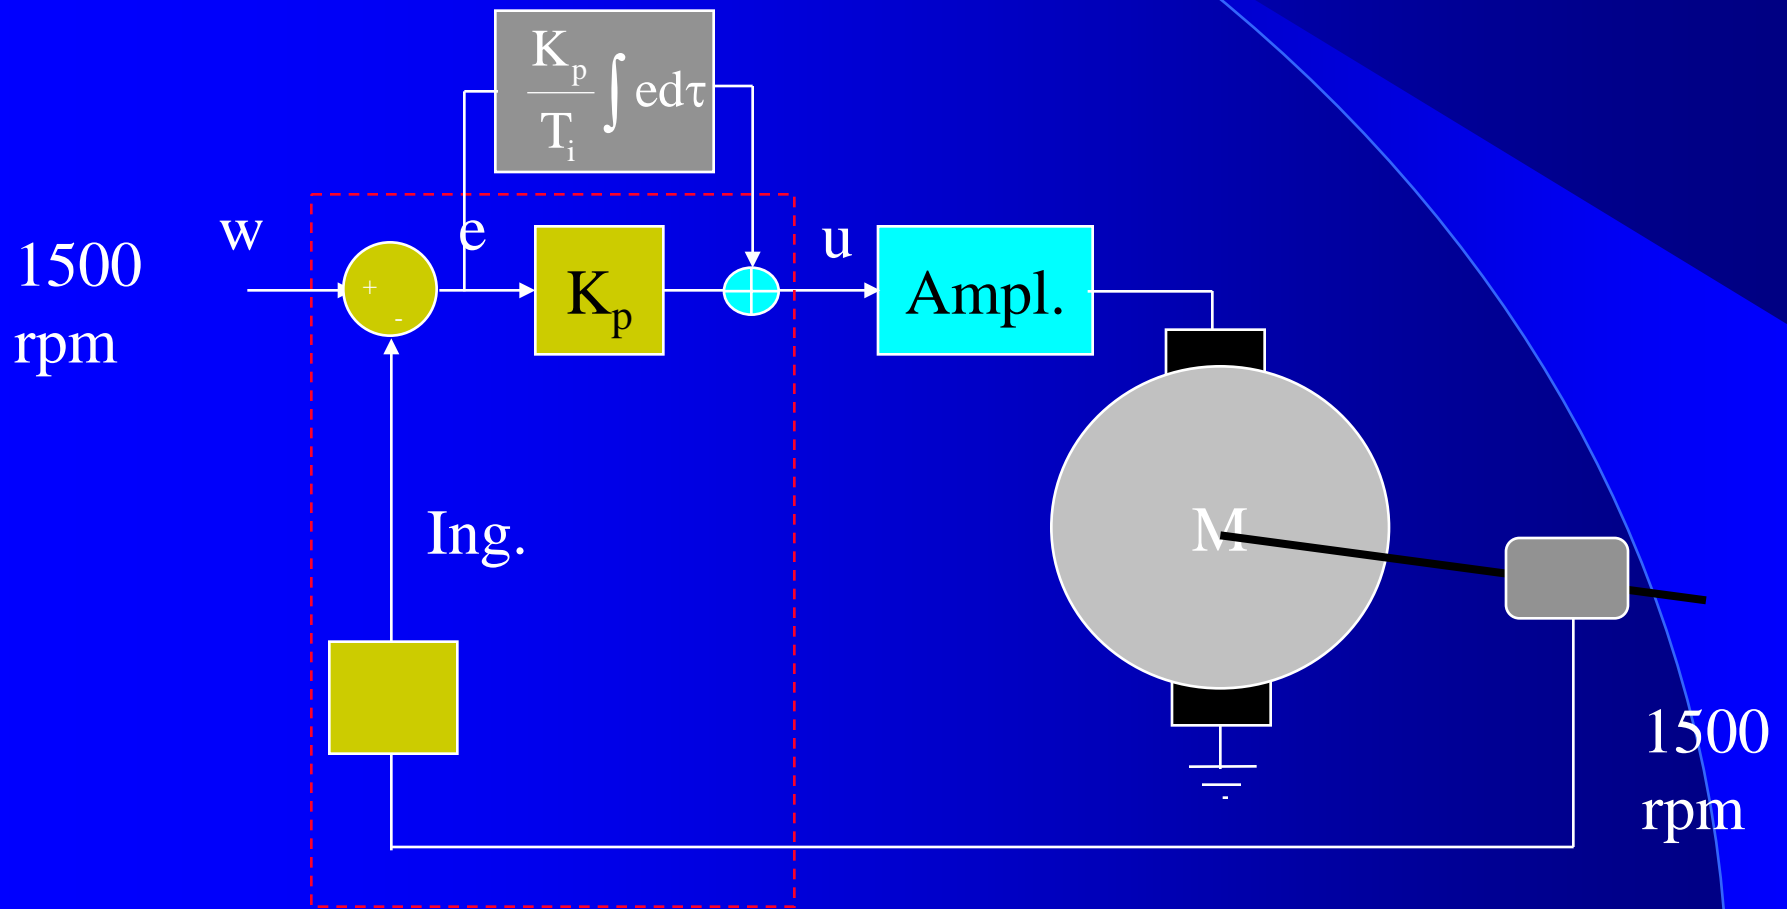

Proportional action

$$e(t) = w - y$$

$$u(t) = K_p e(t) + \text{bias}$$

Integral action

PI

$$e(t) = w - y$$

$$u(t) = K_p e(t) + \text{bias}$$

Integral action (automatic reset)

A P controller does not get steady zero error with self-regulated processes

The integral term changes continuously the control signal until the error is zero

Integral action

$$u(t) = \frac{K_p}{T_i} \int_0^t e(\tau) d\tau$$

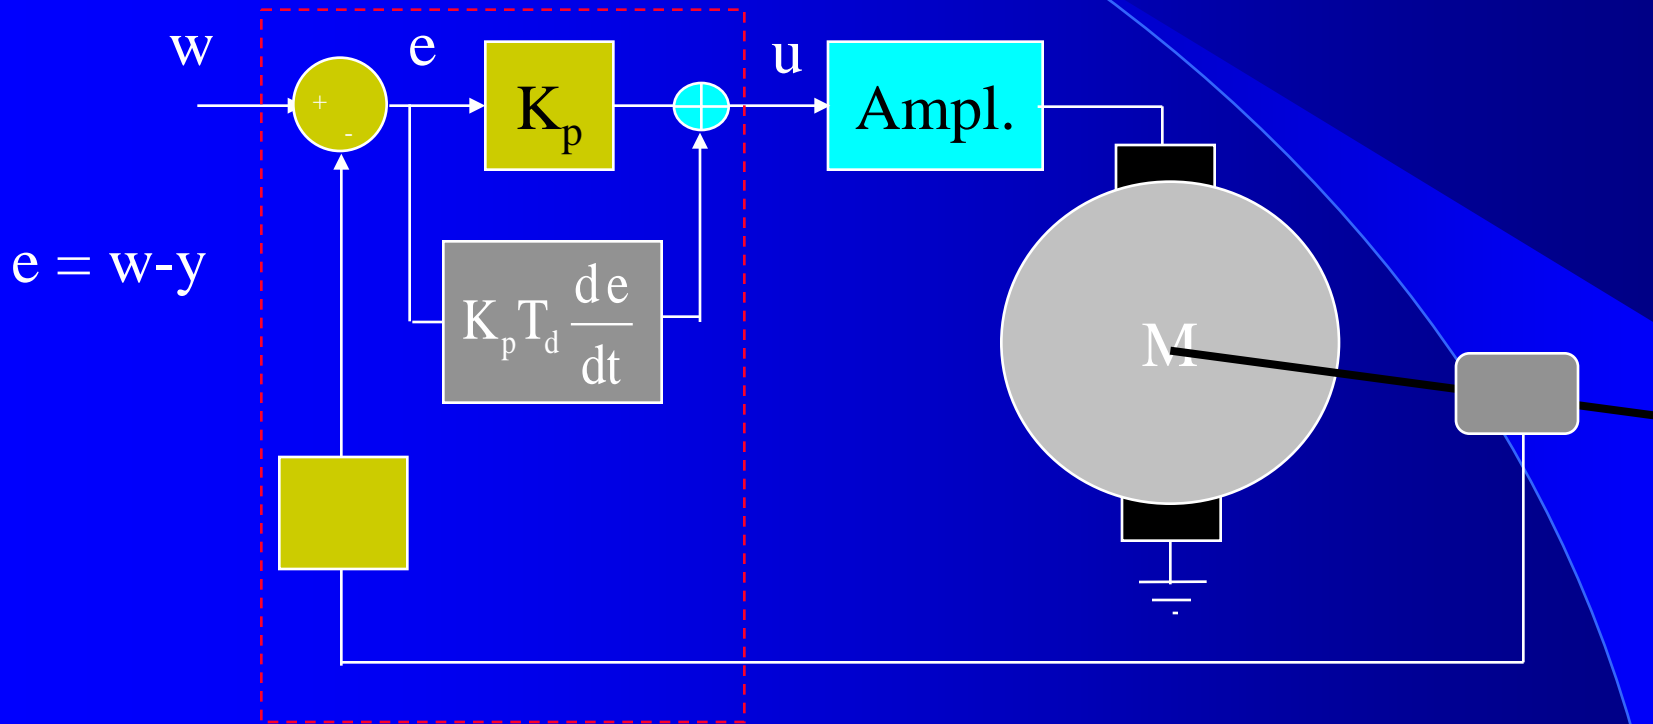

$T_i = 1$ repetition

$$\frac{K_p}{T_i} \int e d\tau = \frac{K_p}{T_i} et = K_p e \Rightarrow t = T_i$$

The integral action will equate the proportional one in T_i time units if e is constant (one repetition)

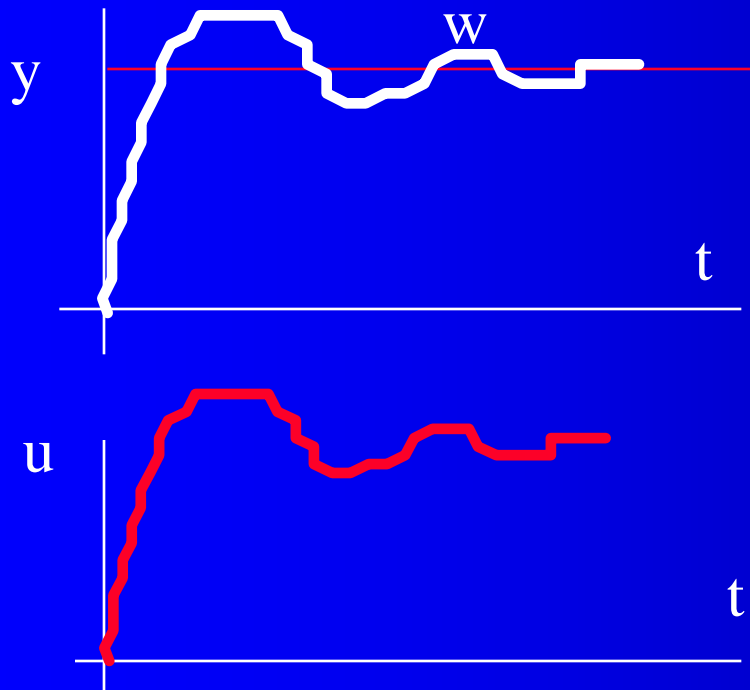

Derivative action

The derivative term will smooth sharp changes in the control signal due to fast changes in the error

$$e = w - y$$

Derivative action

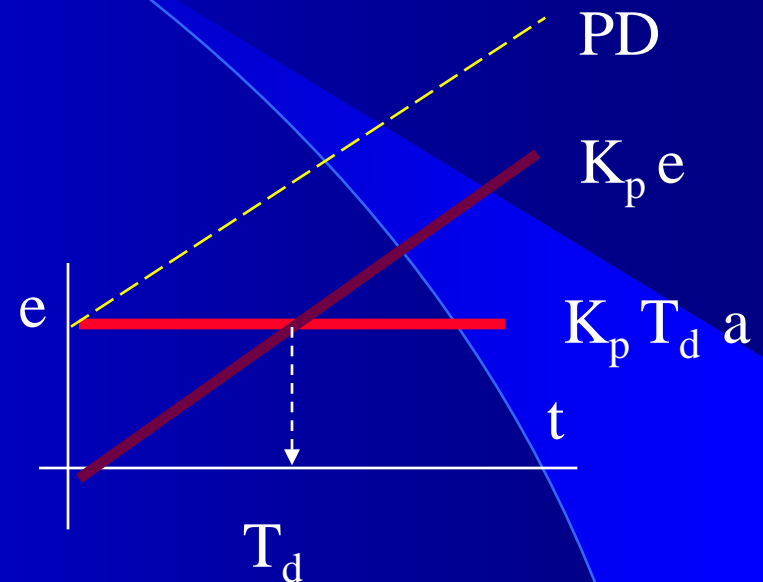

A P controller tuned with high gain in order to get a fast process response can generate too strong u changes and oscillations

If e decreases very fast, the derivative term will decrease u , avoiding oscillations

Derivative action

$$u(t) = K_p T_d \frac{de}{dt}$$

If e changes linearly, the derivative term will equate the proportional one after T_d time units

The derivative action has no influence in the steady state

Derivative action

$$u(t) = K_p T_d \frac{de}{dt}$$

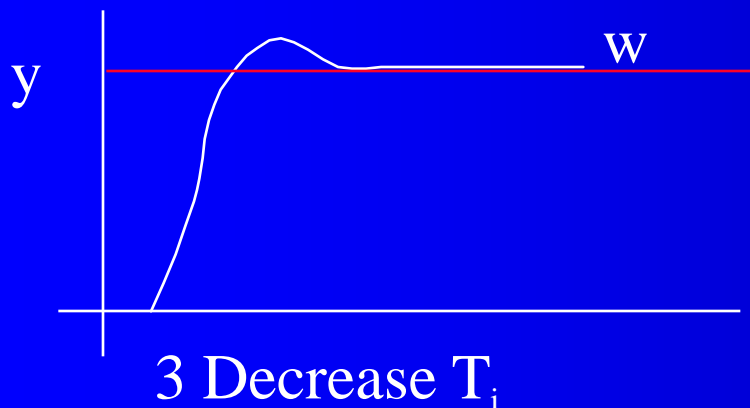

After T_d time units,
derivative and
proportional terms will be
equal if $e = a.t$.

$$K_p T_d \frac{de}{dt} = K_p T_d a = K_p a t \Rightarrow t = T_d$$

PID tuning methods

- Trial and error
- Experiment based
 - Estimate certain dynamic characteristic of the process
 - Compute the PID parameters using tables and the estimated process dynamics
- Model based
 - Error Index minimization
 - Phase margin,....

Trial and error

Start with low K_p , and without integral or derivative actions

Increase K_p until a nice response shape is obtained without excessive control action

Increase a bit T_d and K_p in order to improve the shape of the response

Decrease T_i until the steady state error has disappeared

Process Dynamics

Dynamic response

- Experimentation
- Mathematical model

Dynamic response

Types of processes

Self-regulated

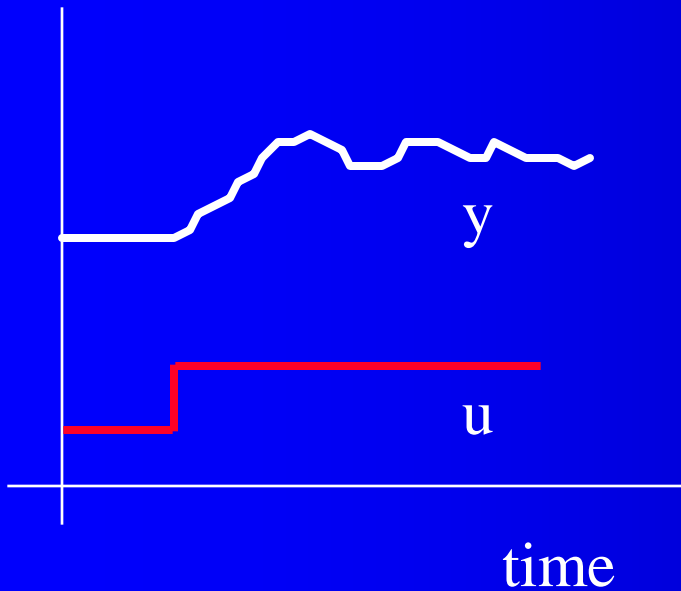

Integrative or non self-regulated

Types of processes

Minimum phase

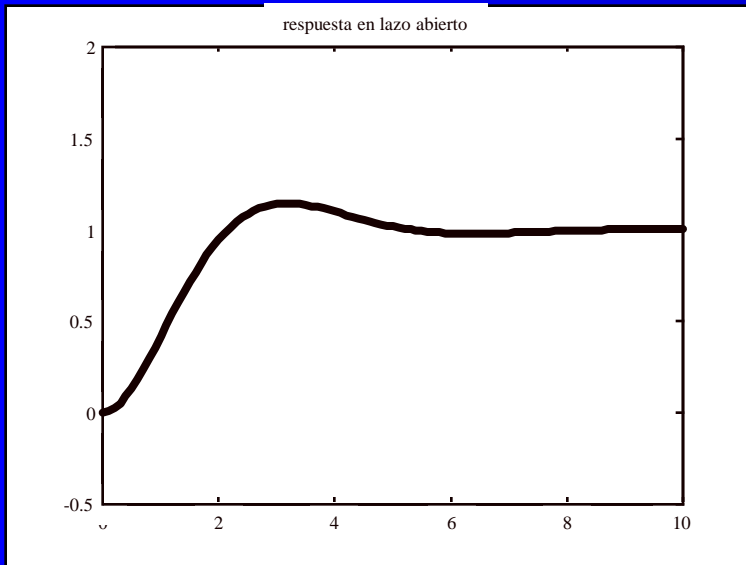

Non-minimum phase

Stability

y

Stable

y

Unstable

Bounded input \rightarrow Bounded output

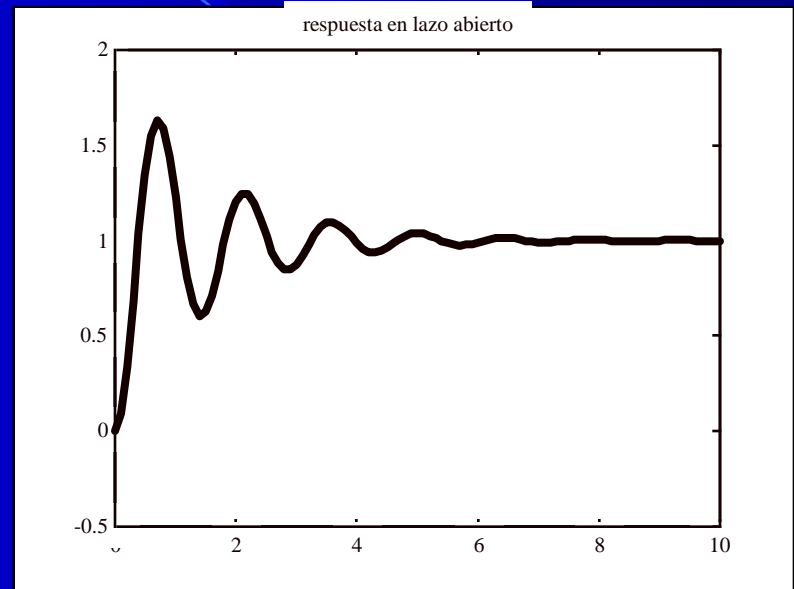

Damping

y

Over-damped

y

Under-damped

Dynamic response

Dynamic response

Overshoot in % = $100 M_p / \Delta y$

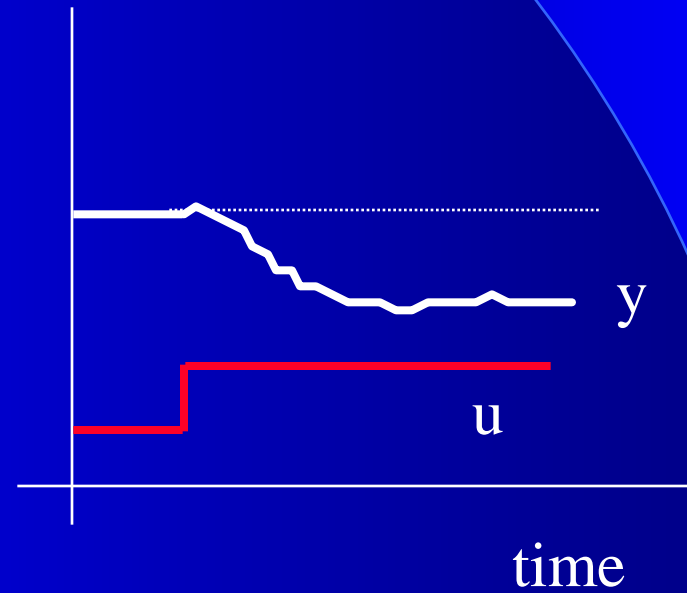

Gain = $\Delta y / \Delta u$

Gain

Positive gain

Negative or inverse gain

Dynamic response

Oscillation period
